

Vectors & Transformations

Prepared by Nikolas Agisilaou

Vectors: The Basics

A **vector** has **magnitude** (size) *and* **direction**; a **scalar** has size only.

- **Notation:** $\overrightarrow{AB}$, bold **a** / underlined $\underline{a}$, or column $\begin{pmatrix} x \\ y \end{pmatrix}$.
- **Column vector:** top = horizontal (+ right, - left); bottom = vertical (+ up, - down).
- **Between points:** $\overrightarrow{AB} = \begin{pmatrix} x_2 - x_1 \\ y_2 - y_1 \end{pmatrix}$ (end - start).
- **Reverse:** $\overrightarrow{BA} = -\overrightarrow{AB}$ (same size, signs flip).

Magnitude & Scalar Multiples

Magnitude (length) by Pythagoras:

$$|\mathbf{a}| = \sqrt{x^2 + y^2} \quad (\geq 0)$$

- **Add / subtract:** componentwise, $\begin{pmatrix} a \\ b \end{pmatrix} \pm \begin{pmatrix} c \\ d \end{pmatrix} = \begin{pmatrix} a \pm c \\ b \pm d \end{pmatrix}$.
- **Scalar:** $k \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} kx \\ ky \end{pmatrix}$; $k > 0$ same way, $k < 0$ reversed, length $\times |k|$.
- **Parallel:** $\mathbf{b} = k \mathbf{a}$ (one is a multiple of the other).

Position Vectors & Vector Geometry

Position vector of $P = (x, y)$: $\mathbf{p} = \overrightarrow{OP} = \begin{pmatrix} x \\ y \end{pmatrix}$

Route rule (end - start): $\overrightarrow{AB} = \mathbf{b} - \mathbf{a}$

Midpoint M of AB : $\mathbf{m} = \frac{1}{2}(\mathbf{a} + \mathbf{b})$

Collinear A, B, C ? Show $\overrightarrow{AC} = k \overrightarrow{AB}$ (a scalar multiple) with a **shared point** $\Rightarrow$ they lie on one line. The value of k is the **length ratio** ($AC = k AB$).

The Four Transformations at a Glance

Transformation	What it does	Describe it fully with	Image is
Translation	slides (no turn/resize)	the column vector $\begin{pmatrix} x \\ y \end{pmatrix}$	congruent
Reflection	flips over a mirror line	equation of the mirror line	congruent
Rotation	turns about a point	angle + direction + centre	congruent
Enlargement	resizes from a centre	scale factor k + centre	similar
Congruent = same size & shape (translation, reflection, rotation). size (enlargement).			Similar = same shape, different

Coordinate Rules (about the origin)

Reflections		Rotations & more	
Mirror line	Rule $(x, y) \rightarrow$	Transformation	Rule $(x, y) \rightarrow$
x -axis ($y = 0$)	$(x, -y)$	90° anticlockwise	$(-y, x)$
y -axis ($x = 0$)	$(-x, y)$	90° clockwise	$(y, -x)$
$y = x$	(y, x)	180° (either way)	$(-x, -y)$
$y = -x$	$(-y, -x)$	270° anticlockwise	$(y, -x)$
$x = a$ (vertical)	$(2a - x, y)$	Translate by $\begin{pmatrix} a \\ b \end{pmatrix}$	$(x + a, y + b)$
$y = b$ (horizontal)	$(x, 2b - y)$	Enlarge, centre C	$C + k(P - C)$

Common Traps & Pitfalls

- Direction Trap:** $\overrightarrow{AB} \neq \overrightarrow{BA}$; $\overrightarrow{BA} = -\overrightarrow{AB}$ (flip both signs).
- Negative-Square Trap:** in $|a|$, $(-4)^2 = +16$, **not** -16 . Length is never negative.
- Rotation Trap:** always give a **direction** — 90° clockwise and anticlockwise land in different places.
- Mirror-Line Trap:** $y = x$ swaps $(x, y) \rightarrow (y, x)$; $y = -x$ swaps *and* negates $(x, y) \rightarrow (-y, -x)$.
- Centre Trap:** enlargement distances are measured **from the centre**, not the origin (unless the centre *is* the origin).
- “Describe fully” Trap:** give **one** transformation with all its details — naming two usually scores zero.

Quick Exam Shortcuts

Describe fully: Translation $\rightarrow$ vector; Reflection $\rightarrow$ mirror line; Rotation $\rightarrow$ angle + direction + centre; Enlargement $\rightarrow$ scale factor + centre.

Combining transformations: two reflections in **parallel** lines = a **translation**; two reflections in **intersecting** lines = a **rotation** about the crossing point; enlargement with $k = -1$ = a 180° **rotation** about the centre.

Working backwards: the **mirror line** is the perpendicular bisector of any point–image join; the **centre of enlargement** is where rays through matching vertices meet, with $k = \frac{\text{image length}}{\text{object length}}$ (negative k if the image is inverted).
